The Geography of Job Tasks

Enghin Atalay Sebastian Sotelo Daniel Tannenbaum*
February 27, 2021

Abstract

We present new facts about the geography of work using online job ads and introduce new measures of job tasks, technology requirements, and the degree of specialization within firms or occupations. We show that the (i) intensity of interactive and analytic tasks, (ii) technological requirements, and (iii) task specialization all increase with city size. The gradient for tasks and technologies is steeper for jobs requiring a college degree. We show that these facts help account for the urban wage premium, both in aggregate and across skill groups.

JEL Codes: J20, J24, R12, R23

Tannenbaum: Department of Economics, University of Nebraska-Lincoln. We thank Reid Gahan and Ryan Kobler for outstanding research assistance and Barbara Nordin for excellent editorial assistance. We thank seminar participants at the annual meetings of the Society of Labor Economists and the Urban Economics Association, the UNL labor reading group, Jeffrey Lin, and Gregor Schubert for valuable feedback. We thank the Washington Center for Equitable Growth and the Russell Sage Foundation (grant #92-18-05) for financial support. Sotelo thanks the IES at Princeton for its hospitality during part of this research. The views expressed in this paper are solely those of the authors and do not necessarily reflect the views of the Federal Reserve Bank of Philadelphia or the Federal Reserve System.

1 Introduction

Rural-urban inequality in the United States has been widening since the 1980s, as economic growth has increasingly concentrated in large cities (Moretti, 2013; Diamond, 2016; Giannone, 2019; Eckert et al., 2019). These broad geographic trends mask the fact that workers at different education levels have fared differently: The urban wage premium, which was equally steep for college and non-college-educated workers in the 1970s and 80s, has flattened for non-college workers since the 2000s (Baum-Snow et al., 2018; Autor, 2019).

Understanding the forces behind the productivity gains in cities and the erosion of these gains for workers without a college degree is a critical input in the design of policies ranging from local taxation to incentives for worker mobility. But while economists have studied the many ways productivity relates to location, prior research has been limited in its ability to characterize the geography of work by both the available data sources and their measures of job tasks and technologies.

One key measurement challenge is that job tasks and technologies are typically measured at the occupation level, using nationwide surveys such as O*NET. Using an occupation-level dataset, it is not possible to measure the extent to which the content of occupations varies across markets. In this paper we fill this measurement gap. We study the geography of job tasks and technology requirements in the United States, using a novel approach to measurement and a new data source: the text of online job ads published between 2012 and 2017. Our task and technology measures are not fixed at the occupation level, and allow for heterogeneity within and across regions. As we show in this paper, work is different in cities, even within occupations, and this heterogeneity is important for understanding both the urban wage premium and the larger skill premium in urban areas.

We take two approaches to task measurement. The first approach, following our prior work on newspaper job postings (Atalay et al., 2018, 2020), maps words in job descriptions into routine and non-routine task categories. Our second approach uses tools from natural language processing to define tasks as verb-noun pairs in the job description, thus imposing fewer ex ante restrictions on the classification of tasks. This second approach departs from prior task literature, in which it is common to select a subset of survey questions from O*NET and classify these items into economically meaningful task categories (Autor, 2013). There are two key advantages to our more granular approach to task measurement: First, it reduces the amount of researcher discretion in classifying tasks, and second, it allows us to measure how specialized jobs are—i.e., how far apart workers are in task space, within firms or occupations.

Our main empirical analysis presents several new facts regarding the geography of work

in the United States. We first show that analytic and interactive tasks have a steep positive gradient in market size. For example, relative to the bottom population decile, commuting zones in the top population deciles have 0.20 to 0.30 standard deviations higher intensity of non-routine analytic and interactive tasks. This gradient remains significant even after conditioning on narrowly defined occupation categories (six-digit SOC codes), and hence is not merely driven by the composition of occupations across markets. We further decompose interactive tasks into those that capture interactions outside the firm and those that capture interactions within the firm. We find that the market size gradient is positive for both external and internal interactive tasks, and that this relationship is more pronounced for jobs requiring a college degree.¹

We next consider whether technological requirements, as measured by the appearance of O*NET's Hot Technologies, are more likely to be mentioned in job descriptions in larger markets, and how this gradient differs for high- and low-skilled jobs. We find a positive gradient of technological requirements with respect to market size. The mean number of technologies mentioned per job ad is 0.11 and it is approximately 2.5 times higher in the 7th through 10th deciles. About 15 percent of the gradient remains after conditioning on six-digit occupational categories. Moreover, the technology gradient is only present for jobs requiring a college degree, and vanishes for jobs requiring only high school. This provides evidence that technologies are an important mechanism behind the flattened urban wage premium for non-college workers (Autor, 2019). Aligned with this interpretation, the technologies with the steepest gradient for college degree holders involve computer programming (e.g., Python, Javascript, and Linux), while for high school degree holders they involve data entry and word processing (e.g., Microsoft Excel, Microsoft Outlook, Microsoft Word) and social media (e.g., LinkedIn, Facebook).²

Our paper also introduces a novel approach for measuring the degree of specialization using the content of job descriptions. Specifically, we first extract verb-noun pairs from the job description text to measure tasks at a more granular level. We then measure the degree of specialization between two jobs as the cosine dissimilarity between vectors representing their task contents. We show that task specialization is increasing in market size and that this relationship is stronger for firms in the nontradable sector.

¹We also show that jobs that are jointly intensive in interactive and analytic tasks are overrepresented in large markets. Thus, the increasing aggregate importance of social and analytic tasks since the 1980s (Deming, 2017) is mirrored by the differential task content between rural and urban labor markets.

²These results complement an expanding literature on the spatial distribution of technology adoption. Eckert et al. (2019) emphasize the impact of cheaper ICTs on services that agglomerate in large cities and focus on the creation and communication of information. Bloom et al. (2020) examine where new technologies develop and how they diffuse.

Finally, we evaluate whether our new technology and specialization measures help explain differences in wages and skill premia between smaller and larger labor markets. We find that within-occupation heterogeneity in technology usage and specialization accounts for 4.2 log points (out of a total of 30.1 log points) of the difference in wages between workers in top and bottom population decile commuting zones, 6.8 log points (out of a total of 40.9 log points) when we subset to white collar occupations.

Our paper contributes to the literature that studies the geography of job tasks and technologies (e.g., Frank et al., 2018). Our measures capture heterogeneity within occupations and across geography, which has been unavailable in prior work. Part of the literature on tasks also exploits job vacancy postings across different labor markets (Hershbein and Kahn, 2018; Deming and Kahn, 2018; Hemelt et al., 2020). We contribute to this literature by introducing a new approach to task measurement, which uses natural language processing and requires fewer ex ante restrictions relative to widely used O*NET scales and categories. Our new measures reveal that both the task content and the technology requirements of occupations shift from rural to urban markets, which suggests there are limits to worker mobility, even within the same occupation.

Recent work also explores interactions between workers as a source of agglomeration, both theoretically (Davis and Dingel, 2019) and empirically (Bacolod et al., 2009; Michaels et al., 2018). Our contribution to this second literature is to provide new evidence, using the finest level of detail available on the nature of work, on the mechanisms underlying the urban productivity gains from increased interaction. We show not only that interactions increase in city size, but also that cities are a locus of interactions both within and across firm boundaries. Furthermore, these relationships with city size are larger for high-skilled work. These findings are new to the literature, and show that differences in interaction intensities help account for the differing returns to employment in large cities by skill group.

We also contribute to the literature that relates productivity and the division of labor to the extent of the market (Young, 1928; Stigler, 1951; Kim, 1989; Becker and Murphy, 1992). Recent work finds greater occupational diversity in cities (Duranton and Jayet, 2011; Tian, 2019). Our contribution is to measure the degree of specialization beyond occupations and to show that increased specialization in cities accounts for a substantial portion of the urban wage premium.

2 Data and Measurement

Our data source is a comprehensive database of online job ads, posted between January 2012 and March 2017, which we purchased from Economic Modeling Specialists International

(EMSI, 2017). This dataset is similar to Burning Glass, which has been used in recent work to study the labor market (Hershbein and Kahn, 2018; Deming and Kahn, 2018; Modestino et al., 2020). Like Burning Glass, our data are proprietary and assembled using web crawlers that extract job vacancy postings from all major online job boards, and de-duplicates postings that appear across boards. A virtue of the EMSI data is that it contains all of the original job ad text. To reduce computational time, we use a 5 percent random sample of the data that contains 7.2 million ads.³

In addition to the full text content of each ad, the data include information EMSI extracts from the postings, including the educational requirement of the job, the firm name (which we use to create firm identifiers), the firm's industry (six-digit NAICS), the occupation code (six-digit SOC), and the job location (county FIPS code). We map FIPS codes to commuting zones (CZs) following Autor et al. (2019). We adopt the CZ as our geographic unit of analysis and refer to CZs throughout as local labor markets. Appendix A.1 provides descriptive statistics for the CZs in the sample, including population and number of ads by CZ employment decile. We exclude ads with fewer than the 1st and more than the 95th percentile word count.⁴ We make a few additional minor restrictions, which are detailed in Appendix A.2, and which leave us with a sample of 6.3 million ads for the occupational analysis and 5.6 million ads for the firm-level analysis.

For the several exercises that require wages at the occupation level and for the construction of employment weights, we use the 2010-2017 American Community Survey (ACS) (Ruggles et al., 2020), and restrict the sample to full-time, full-year workers, defined as working at least 40 weeks in the past year and 35 or more hours per week. We apply a chain-weighted price deflator for personal consumption expenditures to wages before averaging at the four-digit SOC. We link job ads data to the ACS by four-digit SOC and CZ.

We assess the representativeness of the online ads data in Appendix A.3, comparing our data with the Job Openings and Labor Turnover Survey (JOLTS) dataset. We find broad concurrence in the vacancy shares across industries, suggesting that online vacancies measure a fairly representative cross-section of total vacancies.

³EMSI is our preferred data source because it contains the complete job description text, which is ideal for extracting job tasks and measuring specialization. By contrast, Burning Glass provides a combination of tasks, skills, and technologies. Nevertheless, we reproduce our main results using Burning Glass data and report them in Appendix C.4. Our results are similar with this alternate data source.

⁴Dropping extremely short ads removes those that are unlikely to have meaningful task information, while dropping exceedingly long ads helps reduce computation time.

2.1 Measuring Tasks: Classification and Extraction

We extract job tasks from the job descriptions using two approaches. Our first approach follows our earlier work (Atalay et al., 2018, 2020) and maps keywords in the job descriptions to task categories. Our main analysis maps words into five task categories—non-routine interactive, non-routine analytic, non-routine manual, routine cognitive, routine manual—following the categorization of Spitz-Oener (2006). We also map words into O*NET work activities. See Appendix A.4 for more details on the word mappings. For job ad j and task category k, our measure of task intensity is the number of distinct task-specific word mentions per 1,000 ad words. We standardize each task to have mean zero and standard deviation one across all ads. 6

Our second approach is novel and uses verb-noun pairs in the job descriptions to define the set of job tasks. This approach avoids using a researcher-defined mapping of words to task categories and leverages the rich database of text using tools from natural language processing. An additional advantage of this approach is that it defines tasks at a highly granular level, allowing us to carefully measure the degree of specialization of jobs that share the same occupational code.

We describe this approach in detail in Appendix B and briefly outline it here. A task is defined as a (verb stem, noun stem) pair, such as "assist customers" or "provide advice." We stem verbs and nouns so that variation in verb and noun forms do not affect the analysis. We extract the task categories as follows: (i) we first identify the section of ad text that refers to job tasks, and (ii) within this section of text, we find each verb and the next noun that appears in the sentence, ignoring other parts of speech that may appear in between. For our analysis, we extract the 500 most common verb-noun pairs. Once we have assembled the set of tasks, we represent each job ad as a vector, of which each element corresponds to a distinct task. Verb-noun pairs that appear multiple times in an ad are counted only once, and hence each element is a zero or one. We exclude 70 verb-noun pairs that in our judgment do not correspond to job tasks, such as "send resume" and "is position," and hence the number of tasks used in the analysis is 430. The 10 most common tasks, from most to least frequent, are: "written communication," "perform duties," "working team," "provide customer_service,"

⁵We count repeated use of the same word only once. Hence, the repetitiveness of the job description does not inflate the task intensity of the ad. The use of different task keywords, such as "analyze" and "evaluate," will each be counted and will increase the task intensity measure.

⁶In Atalay et al. (2020), we show robustness to the choice of word mappings—e.g., by including and excluding synonyms of words in the mapping to tasks, and to alternative task units.

 $^{^{7}}$ We choose 500 tasks to balance the advantage of comprehensively characterizing jobs' tasks against the costs of computational time. We reproduce the key specialization results using the 300 most common tasks, in Appendix C, and obtain similar results.

"be part," "provide service," "work environment," "perform functions," "build relationships," "ensure compliance." While the task extraction process is not perfect, a key strength of our approach is that it allows the natural text used by employers, describing the jobs they intend to fill, to define the set of tasks.

2.2 Validation of Data and Task Measures

We demonstrate that information contained in the online ad text captures real information about the labor market in Appendix A.5. We compare the education requirements extracted from the job ads with the education of employed workers in the 2010-2017 ACS in the same occupation-market. We find that these two measures of education are highly correlated—a relationship that holds across large and small markets, within and across occupations.

We also validate the task measures extracted from the ads and compare these measures with O*NET. First, in Appendix A.4 we show that occupation-level measures of O*NET Work Activities, which we construct from the text of online ads, are highly correlated with those occupations' measures in the O*NET database. Second, in Appendix B.6, we show that our task measures, constructed using either of the two approaches, account for variation in average wages at the occupation level, above and beyond what is captured by occupation fixed effects. These task measures therefore capture occupational characteristics beyond what is available in O*NET, and these characteristics are reflected in market wages.

3 The Geography of Tasks and Technologies

This section presents the main analysis of the geography of job tasks, technology requirements, and worker specialization.

3.1 Job Tasks Across Space

We begin with our first approach to task measurement and study how the five task categories (non-routine interactive, non-routine analytic, non-routine manual, routine cognitive, and routine manual) differ across labor markets of different sizes. For each task k, we regress task intensity $t_{jn}^{(k)}$ of job j in market size decile n on indicators for market size decile. CZs are placed in market size deciles using employment weights so that each decile n has approximately the same number of employed workers. We estimate:

$$t_{jn}^{(k)} = \beta_0 + \sum_{n=2}^{10} D_{jn} \beta_n^{(k)} + \gamma' x_{jn} + \epsilon_{jn}, \tag{1}$$

where D_{jn} are indicators for market size decile n, with the 1st decile serving as the reference group, and x_{jn} represents a control for ad length and, in some specifications, six-digit SOC fixed effects. The coefficients of interest, $\beta_n^{(k)}$, capture the task intensities relative to the 1st decile market size. Standard errors are clustered at the commuting zone level.

Figure 1 plots the coefficients on market size decile, $\beta_n^{(k)}$. The primary takeaway is that non-routine interactive and non-routine analytic tasks are increasing in market size, while routine manual tasks are decreasing in market size. The 10th population decile has 0.20 s.d. greater intensity of non-routine interactive tasks and 0.30 s.d. greater intensity of non-routine analytic tasks, while having approximately 0.20 s.d. lower intensity of routine manual tasks. The right panel includes six-digit SOC fixed effects, and shows that the gradient diminishes. This weaker gradient is unsurprising and indeed reassuring, since occupational categories are designed to group jobs by their work activities. Nevertheless, even within occupations, non-routine interactive and analytic tasks are mentioned more frequently (by 0.05 s.d.), and routine manual tasks are mentioned less frequently (by 0.08 s.d.), in the top population decile CZs relative to the bottom decile CZs. Hence, while much of the variation in job tasks across geography is captured by the composition of occupations, a strong gradient remains even within occupations, which is missed in standard data sources such as O*NET.⁸

Figure C.1 presents the analysis for interactive and analytic tasks separately by the education requirement of the job ad. Jobs requiring a college degree in urban areas are far more intensive in interactive and analytic tasks compared with rural areas, while this gradient is flat for jobs requiring only a high school degree. Figure C.2 shows that jobs that are jointly intensive in interactive and analytic tasks represent a greater share in large markets, which mirrors these jobs' increasing importance over time (Deming, 2017). Jobs that are intensive in both analytic and interactive tasks make up 15 percentage points more of jobs in each of the highest three deciles compared with the lowest decile. Jobs that are intensive in only analytic tasks but not interactive tasks make up only about 4 percentage points more of jobs in the highest three deciles. These qualitative findings also hold within occupations.

Interactive Tasks Inside and Outside the Firm

Having demonstrated the importance of interactive tasks in urban labor markets, we study the nature of interactive tasks and specifically assess the importance of interactions *inside*

⁸We perform a simple decomposition in Appendix C.1 to quantify how much of the variation in job tasks across city size is within versus between occupations. Between the top population quartile and bottom population quartile CZs, 35 percent of the difference in non-routine analytic task intensity occurs within occupations. For the other four task measures, this fraction ranges from -6 percent (for routine cognitive tasks) to 50 percent (for non-routine manual tasks).

the firm relative to interactions *outside* the firm. Our findings speak to a recent theoretical and quantitative literature that emphasizes worker interactions and information flows as sources of productivity differences across geographies, firms, and worker types (Garicano and Hubbard, 2009; Garicano and Rossi-Hansberg, 2015; Davis and Dingel, 2019).

We use task measures that map to O*NET task categories that separately measure external and internal interactive tasks. We regress each task-intensity measure on commuting zone size deciles, with controls for ad length and, where indicated, six-digit SOC fixed effects. Figure 2 plots the coefficients on market size decile, with the 1st decile as the reference decile. The results show that the gradient of external tasks with market size is stronger than that of internal tasks. Compared with ads in the bottom population decile, ads in the top population deciles mention internal interactive tasks (by 0.20 s.d.) and external interactive tasks (by 0.25 s.d.) more frequently. When we include six-digit SOC occupation fixed effects, the gradients are substantially smaller, though still economically and statistically significant. In Figure C.3, we show that this gradient is largely driven by jobs requiring a college degree.

A Granular Approach to Measuring Tasks

In our second approach, we refine our task measurements using a more granular set of job tasks, which are verb-noun pairs extracted from the text. We estimate equation (1) separately for each of the tasks, and collect the coefficients $\hat{\beta}_{10}^{(k)}$, which captures the relative difference in task k intensity between 10th decile market size and 1st decile market size. The coefficients are normalized by dividing by the standard deviation of the task and then sorted by magnitude. Table B.4 presents the largest positive and largest negative estimates across all tasks.

Our results echo, at a much higher resolution, what we found in Figure 1. Placing little guidance on the categorization of tasks, and using the natural language of the job ad descriptions to measure tasks, this exercise reveals that non-routine and abstract tasks have the steepest positive gradient. Examples include "managing projects," "problem-solving skills," and "developing strategies." Communication and group interactions are important, too, as illustrated by the importance of "written communication" and "maintaining relationships." The tasks with the steepest negative gradient reflect more routine activities and emphasize following directions, including "operate cash-register," "greeting customers," and "maintain-

⁹We define external interactive tasks as O*NET activities "Selling or Influencing Others" and "Communicating with Persons Outside Organization," and we define internal interactive tasks as O*NET work activities "Guiding, Directing, and Motivating Subordinates," "Developing and Building Teams," "Coaching and Developing Others," "Coordinating the Work and Activities of Others," and "Communicating with Supervisors, Peers, or Subordinates." We list the word mappings in Appendix A.4.

3.2 Technology Requirements Across Space

In the previous section, we showed that interactive tasks are more prevalent in urban environments. Past work, which hypothesizes that human interaction is a key input in innovative activity and draws on patent data or occupational titles, has documented that new technologies are first introduced and adopted in cities (Carlino et al., 2007; Lin, 2011). In this section, we systematically explore which technologies are more important in cities and how this relationship varies with the human capital of workers.

We consider two questions: Are technological requirements more important in urban areas? And how does the technology gradient differ for jobs requiring a college degree compared with the gradient for jobs requiring a high school degree?

We measure the technology requirements of a job by searching for each of O*NET's Hot Technologies. The list is originally derived from job postings and includes 180 different technologies. 11 As a preliminary exercise, we examine which technologies have the steepest positive gradient with respect to labor market size and which have the steepest negative gradient. We estimate equation (1), replacing the dependent variable with $tech_{in}^{(\ell)}$, an indicator for job ad j in market size decile n requiring technology ℓ . We run this regression for each of the 180 technologies, and sort by $\beta_{10}^{(\ell)}$, after normalizing the estimates by dividing by the standard deviation of $tech_{jn}^{(\ell)}$. The results are presented in Appendix B. The technologies with the steepest positive gradient with market size are Microsoft Excel, Python, Microsoft Project, and Linux. Separating the analysis by whether the job requires a college degree or a high school degree only, we find that the positive gradient is steeper for jobs requiring a college degree. For college workers, the 15 technologies with steepest gradients have gradients 1.5 to 2 times as large as the 15 technologies with steepest gradients for non-college workers. Moreover, for college workers the technologies with the largest gradient in city size involve computer programming (e.g., Python, Javascript, Linux), while for non-college workers they involve data entry and word processing (e.g., the Microsoft Office suite) and social media (e.g., LinkedIn, Facebook).

Figure 3 presents a job-level regression of the number of technologies that are a job

¹⁰For robustness, in Table B.5 we reproduce this table with six-digit SOC fixed effects. We also reproduce the table using the verb list from Michaels et al. (2018); see Table B.6. Both robustness exercises reveal a similar pattern of increased interactiveness and teamwork in urban areas.

¹¹We list the technologies in Appendix B.3; the list is also available on the O*NET website: https://www.onetonline.org/search/hot_tech/. The initial list contains 182 technologies, but we exclude R and C from our main analysis since they are likely to lead to false positives. Appendix B.5 reproduces the main analysis including R and C. The results are unchanged.

requirement, on CZ size deciles, controlling for log ad length. Panel I is without any occupation controls, and panel II includes six-digit SOC fixed effects. Panel I shows an increase in technological requirements with labor market size. Note that the technology gradient only appears for jobs requiring a college degree. Panel II shows that approximately 15 percent of the gradient remains after including six-digit SOC fixed effects. Once again, the gradient is present only for jobs requiring a college degree.

3.3 Specialization in Tasks Across Space

Economists since Adam Smith have attempted to understand the forces behind the productivity gains that come from a larger marketplace (Young, 1928; Stigler, 1951; Becker and Murphy, 1992; Garicano and Hubbard, 2009). Smith noted that larger markets allow for workers to specialize in narrower sets of activities and, as a result, become more productive. In this section, exploiting our granular task measures, we provide a new measure of worker specialization: the dissimilarity in tasks that workers perform relative to their peers within the same firm-market or occupation-market. We then demonstrate that this measure of specialization increases with market size.

To study specialization, we first need a notion of distance between jobs in task space. We characterize each job j as a vector of tasks, T_j , with each element corresponding to a distinct task. Each element takes a value of one if job ad j's description contains the corresponding task, and zero otherwise. We normalize the task vectors to have unit length: $V_j = \frac{T_j}{\sqrt{T_j \cdot T_j}}$. The normalization ensures that our measures of specialization are unaffected by job ad length.¹²

The inner product between two task vectors is their cosine similarity, which takes a value between zero and one. Intuitively, if two jobs have perfect overlap in tasks, their similarity is one, and if they share no tasks in common, their similarity is zero. We define the task dissimilarity between jobs j and j' as one minus their cosine similarity: $d_{jj'} = 1 - V_j \cdot V_{j'}$.

Our notion of specialization within the firm-market is the average task dissimilarity between job j and other jobs in the firm-market pair. For this analysis, we denote a firm f as a firm name \times six-digit industry NAICS code.¹³ Define $d_{jfm} = 1 - V_{jfm} \cdot \overline{V}_{(-j)fm}$, where $\overline{V}_{(-j)fm}$ is the vector of average task content in firm-market fm, averaged over all jobs in

¹²In constructing the firm-market sample, we drop ads that contain zero tasks—approximately 15 percent of ads—and ads that are singletons in the firm-market cell, another 4 percent. In constructing the occupation-market sample, the respective numbers are 17 percent and 0.11 percent.

¹³We group by both firm name and industry because the same firm name may, in certain cases, correspond to two separate firms in two different industries. Since these cases are rare, our results are essentially unchanged when grouping by firm name.

the firm-market excluding job j. If the term d_{jfm} is larger, job j has less overlap in task content with other jobs in the firm-market fm. At the firm level, the degree of specialization is $d_{fm} = \frac{1}{n_{fm}} \sum_{j \in fm} d_{jfm}$, where n_{fm} is the number of jobs in the firm-market. We emphasize that we cannot construct dissimilarity for all workers in the firm-market but only for vacancies, which capture newly formed jobs.

Note that we can define task dissimilarity more generally, $d_{jcm} = 1 - V_{jcm} \cdot \overline{V}_{(-j)cm}$, where c may represent job j's firm or its occupation. In our analysis we explore dissimilarity along these two dimensions. We estimate the following regression:

$$d_{cm} = \alpha_0 + \sum_{n=2}^{10} D_{cmn} \alpha_n + x'_{cm} \delta + \epsilon_{cm}, \qquad (2)$$

where d_{cm} is the mean task dissimilarity in group c and market m (where c refers to either firm or occupation), D_{cmn} is an indicator that market m is in size decile n, and x_{cm} are our main controls averaged to the group-market cell. In specifications in which c refers to occupation, x_{cm} may also include occupation fixed effects.¹⁴

Figure 4 plots the estimates for α_n . The main result in panels I and II is that task dissimilarity in the firm is increasing in market size, with a steeper gradient for nontradable sector firms.¹⁵ This result aligns with the classic theoretical point that the degree of specialization is limited by the extent of the market. Since the market for tradable sector firms extends beyond their CZs, the gradient of specialization with respect to local market size will be flatter for workers in these sectors. Panels III and IV show that specialization within occupations is also increasing in market size.

We study specialization across firms in Appendix C.3, in which the unit of analysis is the industry-market, and specialization is defined as dissimilarity in firm-level average tasks between firms in the same industry-market. Relative to firms in rural markets, firms in urban markets are located further apart in task space.

All of these results together reveal that, as market size grows, there is an increase in both within- and between-firm specialization in tasks.

¹⁴In our analysis of specialization within occupations, we use four-digit (rather than six-digit) SOCs as our unit of analysis, to have more job ads in cells with which to calculate task dissimilarity.

¹⁵As a robustness exercise, we measure the degree of specialization without using the granular task measures and instead examine the distribution of common and rare occupations across space. Occupations that are rare as a share of the entire U.S. labor market make up a greater share of larger markets relative to smaller markets (see Appendix C.3). We also perform the exercise of Tian (2019), showing that in larger markets there are more distinct job titles per firm, conditional on the number of ads posted by the firm.

3.4 Tasks, Technologies, and Wages

In previous sections, we have documented that both technology usage and worker specialization increase with city size. In this section, we show that within-occupation differences in specialization and technology content help account for the urban wage premium.

We compute the mean task dissimilarity within each occupation-CZ pair,

$$d_{om} = \frac{1}{n_{om}} \sum_{j \in om} (1 - V_{jom} \cdot \overline{V}_{(-j)om}),$$

the mean number of technological requirements at the occupation-CZ, $tech_{om}$, and, using our ACS sample, the fraction of employed workers in the occupation-CZ with a BA or above, ba_{om} .

We run the following regression:

$$log(wage)_{om} = \gamma_0 + \gamma_1 d_{om} + \gamma_2 tech_{om} + \gamma_3 ba_{om} + \xi_o + \epsilon_{om}. \tag{3}$$

We include four-digit occupation fixed effects, ξ_o , in some specifications of equation (3) to highlight the role of tasks and technologies in accounting for within-occupation wage differences across markets. The coefficient γ_1 represents the relationship between task dissimilarity and wages. One should be cautious in interpreting γ_1 as causal, since, for example, workers may sort endogenously into occupations by unobservables in local labor markets that may correlate with market size. Nevertheless, it is valuable to assess whether within-occupation differences in tasks account for variation in wages across geography, beyond what is captured by differences in worker skills, and γ_1 is a key parameter for doing so. Similarly, γ_2 is informative about the extent to which technological requirements are important for accounting for within-occupation differences in wages across markets.

Table 1 reports the results. Column 1 shows that a one-standard-deviation increase in task dissimilarity is associated with an increase in wages by 6.9 percent, while a 10-percentage-point increase in the fraction of jobs requiring a technology increases wages by 5.3 percent. Controlling for education in column 2 weakens the relationship somewhat, but technologies and tasks remain economically and statistically significant.

Columns 4-6 re-estimate equation (3) separately by occupational category. We classify workers into white-collar, blue-collar, and service workers by two-digit SOC code, as described in the table note. Within occupation-CZ task dissimilarity plays an important role in accounting for the wage premium for white-collar occupations, but not for blue-collar occupations. Columns 4-6 also show that white-collar workers have a large urban premium for technological requirements, while for blue-collar workers the relationship is negative and

small in magnitude.

We use these coefficient estimates to gauge the importance of our specialization and technology measures in accounting for urban wage premia. Within occupations, workers in the tenth population decile have wages that are 30.1 log points higher than those in the bottom decile. As panel IV of Figure 4 indicates, specialization in top decile CZs is 1.28 standard deviations greater than in bottom decile CZs. Thus, column 3 of Table 1 indicates that our specialization measure accounts for $3.8 \ (\approx 1.28 \cdot 0.03)$ log points of the difference in wages for workers living in top and bottom population deciles. The technology measures account for an additional $0.4 \ (\approx 0.17 \cdot 0.023)$ log points. Together, the two variables account for 14 percent $\ (\approx 4.2/30.1)$ of the urban wage premium. Furthermore, using the coefficient estimates from column 4, the task and technology measures account for 6.8 log points, 17 percent of the 40.9 log point urban wage premium in white collar occupations. In sum, our specialization and technology measures account for a substantial portion of the urban wage premium as well as the steeper urban wage premium for highly skilled workers that exists within occupations.

These empirical findings indicate that the returns to employment in large cities differ for workers in blue- and white-collar occupations. They also suggest that the task content within occupations varies from rural to urban areas, which may limit the mobility of occupation-specific human capital.

4 Conclusion

By bringing in new data and incorporating tools from natural language processing, we examine in detail the differential task and technology content of jobs in urban and rural areas and capture heterogeneity within occupations. We also introduce an approach to define job tasks at a granular level, and use it to characterize the relation between market size and specialization, which is a key economic mechanism for productivity gains that has eluded direct measurement. We view our findings as critical for understanding questions such as what drives the urban wage premium, what are the limits to human capital mobility across regions, and how policies can enhance labor market fluidity.

Figures and Tables

Figure 1: Tasks and Market Size

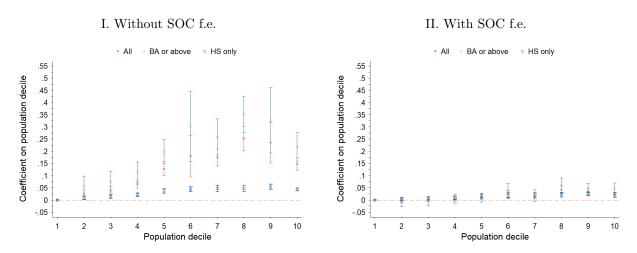

This figure presents estimates of equation (1), which depict the task gradient with market size. We control for log total ad words and, in the right panel, six-digit SOC fixed effects. The dependent variable is task intensity.

Figure 2: O*NET Interactive Tasks Gradient

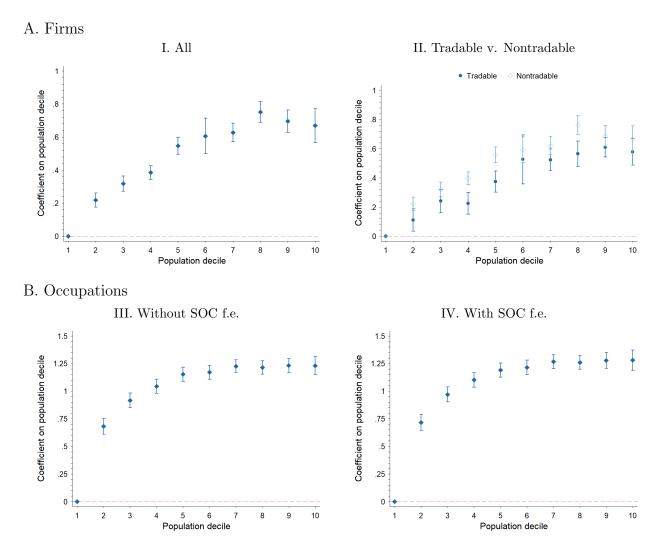

This figure presents the estimates from a regression at the job vacancy level of equation (1). We control for log total ad words and, in the right panel, six-digit SOC fixed effects. The dependent variable is task intensity.

Figure 3: The Technology Gradient

The dependent variable is the number of O*NET Hot Technologies mentioned in the ad, which is regressed on a vector of deciles for CZ. For reference, the 1st decile mean is 0.11 across all job ads, 0.28 for BA or above, and 0.10 for HS only. We control for log total ad words. Panel II includes six-digit SOC fixed effects. Standard errors are robust and clustered at the CZ level.

Figure 4: Specialization Gradient: Task Dissimilarity Within Firms and Occupations

The figures above present estimates of equation (2) and study how task dissimilarity within the firm (panel A) and within the occupation (panel B) vary with market size. Panel A uses the firm-market sample and the dependent variable is the mean task-dissimilarity in the firm-market, while panel B uses the occupation-market sample and the dependent variable is mean task dissimilarity in the occupation-market. We control for log total ad words, which is averaged to the cell level. Firm-market regressions are weighted by number of ads in the cell; occupation-market regressions are weighted by ACS employment in the cell. Standard errors are clustered at the CZ level. For reference, the 1st CZ decile mean for the top left panel is -0.51, and for the top right panel is -0.54 for the nontradable sample and -0.03 for the tradable sample. The 1st CZ decile mean for the bottom two panels is -1.92. We define tradable by two-digit NAICS code: agriculture, forestry, fishing and hunting (11), mining, quarrying, and oil and gas extraction (21), and manufacturing (31-33).

Table 1: Task Dissimilarity, Technologies, and Wages

| | | All | | White-collar | Blue-collar | Service |
|---|--------------------------|------------------------|--------------------------|------------------------|-------------------------|-------------------------|
| | (1) | (2) | (3) | (4) | (5) | (6) |
| Task dissimilarity | 0.069*** (0.004) | 0.057*** (0.003) | 0.030*** (0.002) | 0.049*** (0.004) | 0.006** (0.003) | 0.038*** (0.004) |
| Technology requirements | 0.527^{***} (0.012) | 0.189*** (0.008) | 0.165^{***} (0.025) | $0.219^{***} (0.028)$ | -0.055** (0.027) | $0.064 \\ (0.046)$ |
| BA or above | | 1.067*** (0.027) | 0.872*** (0.070) | 0.941*** (0.077) | $0.479^{***} (0.059)$ | 0.639*** (0.061) |
| SOC f.e. Number of observations | No 45,156 | No 45,156 | Yes 45,156 | Yes 24,447 | Yes 11,338 | Yes 9,130 |
| R ² Mean of dependent var. Mean task dissimilarity | 0.140 10.769 0.000 | 0.536 10.769 0.000 | 0.839 10.769 0.000 | 0.819 10.968 0.158 | 0.580 10.561 -0.169 | 0.670 10.224 -0.408 |
| Mean technology requirements Mean BA or above | 0.247 0.363 | 0.247 0.363 | 0.247 0.363 | 0.322 0.518 | 0.129 0.076 | 0.106 0.132 |

The unit of observation is the occupation-market. The dependent variable is log wages, regressed on occupation-market task dissimilarity (normalized to have mean zero, standard deviation one across jobs), mean number of technologies, and fraction of workers with a BA or above, and, where indicated, four-digit SOC fixed effects. Regressions are weighted by employment. Standard errors are clustered at the CZ level. Occupations are classified into blue-collar, white-collar, and service occupations by two-digit SOC codes as follows. Blue-collar: farming, fishing and forestry (45); construction and extraction (47); installation, maintenance and repair (49); production (51); and transportation and material moving (53). White-collar: management, business and finance (11–13); professional (15–29); sales (41); and office and administrative support (43). Service: healthcare support (31); protective service (33); food preparation and serving (35); building and grounds cleaning and maintenance (37); and personal care and service (39). Military (55) is excluded from columns 4-6.

A Validating the Online Job Ads Data

This section presents supplementary information and validation of the job ads data. Appendix A.1 provides summary statistics on the CZ deciles. Appendix A.2 provides details on the construction and cleaning of the sample used in the paper. Appendix A.3 discusses the representativeness of online vacancies relative to total vacancies as measured in JOLTS. In Appendix A.4, we show that when we create occupation-level task measures from the job ad text that correspond to O*NET task categories, these measures are highly correlated with O*NET importance scales. In Appendix A.5, we show that the education requirements in the job ads data correlate strongly with the education of employed workers in the ACS in the same occupation-market, and that this relationship holds across large and small markets and within and between occupations. In Appendix A.6, we show that while there are trends in job ad length across space—larger markets have longer job ads—once we control for ad length, the gradient of job description keywords with respect to market size becomes economically insignificant.

A.1 CZ Decile Summary Statistics

Table A.1 presents summary statistics by CZ decile, including the total number of job ads in the decile, the median CZ population, and the name(s) of the median population CZ(s) within the decile.

Table A.1: CZ Decile Summary Statistics

| Decile | Total ads | Median CZ pop. | Median CZ name(s) |
|--------|-----------|----------------|--|
| 1 | 506.8 | 54.9 | Norfolk & Madison Counties, NE |
| 2 | 575.0 | 304.7 | Jackson & Hillsdale & Lenawee Counties, MI; Bloomington, IN |
| 3 | 595.2 | 609.6 | Wichita, KS |
| 4 | 599.8 | 1,033.4 | Tulsa, OK; Naples-Marco Island, FL |
| 5 | 732.3 | 1,639.0 | Nashville-Davidson-Murfreesboro, TN |
| 6 | 692.3 | 2,441.2 | St. Louis, MO |
| 7 | 705.1 | 3,453.2 | Minneapolis-St. Paul, MN; Hartford-Bridgeport-Stamford-Norwalk, CT |
| 8 | 858.4 | 5,056.6 | Atlanta, GA |
| 9 | 685.3 | 6,159.5 | Newark-Trenton-White Plains NJ-NY; Houston, TX |
| 10 | 385.4 | 15,273.6 | New York, NY; Los Angeles, CA |

The table above presents summary statistics by CZ decile, including the total number of job ads in the decile (expressed in 1,000s), the median CZ population in the decile (in 1,000s), and the name(s) of the median population CZ(s) within the decile. In cases in which the median CZ population is the average of two CZs, we provide both names.

A.2 Details on Sample Construction

We use a 5 percent sample of the online job ads data we purchased from EMSI. The sample of our dataset covers January 2012 to March 2017. We exclude ads with fewer than the 1st percentile number of words and greater than the 95th percentile number of words. These restrictions ensure that the ads have enough content to measure tasks and also are not so long as to considerably slow processing time. This step limits the sample to ads with length between 11 and 841 words and reduces the sample to 7.0 million ads. We exclude Hawaii and Alaska from the analysis, which drops another 35,529 ads. We also exclude ads that do not contain a county FIPS code, and therefore cannot be mapped to a CZ. This step drops another 503,051 ads. Finally, we drop ads that have no SOC code—another 102,154 ads. This leaves 6.3 million ads for our occupational analysis. Table A.2 presents the number of ads by year in the sample.

For the firm-level analysis sample, we impose a few additional restrictions. We drop ads placed by staffing or placement agencies, since they act as intermediaries between the worker and the firm hiring the worker. This step drops 596,578 ads. ¹⁶ We drop ads without a firm name, which is another 107,317 ads. Finally, we drop firms with a missing NAICS code—another 3,771 ads. These restrictions yield approximately 5.6 million ads for the sample used for the firm-level analysis.

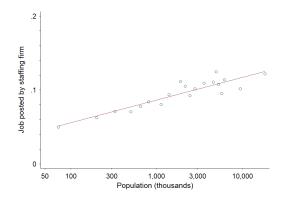

Table A.2: Job Vacancy Counts by Year

| Occupa | tion-level dataset | Firm-le | evel dataset |
|--------|--------------------|---------|--------------|
| Year | Count | Year | Count |
| 2012 | 591,682 | 2012 | 504,618 |
| 2013 | 860,961 | 2013 | 751,387 |
| 2014 | 1,021,805 | 2014 | 904,882 |
| 2015 | 1,465,475 | 2015 | 1,327,579 |
| 2016 | 1,905,368 | 2016 | 1,709,801 |
| 2017 | 490,287 | 2017 | 429,645 |
| Total | 6,335,578 | Total | 5,627,912 |

The table above presents the number of job ads by year after applying the sample restrictions described in Appendix A.2.

¹⁶Figure A.1 presents a binscatter of an indicator for the job ad's being posted by a staffing firm, against the CZ population. The figure shows a slight positive gradient with market size.

Figure A.1: Job Posted by a Staffing Firm

This figure presents a binned scatterplot of an indicator for the job ad's being posted by a staffing firm on log population at the CZ-level.

A.3 Representativeness of Online Vacancies

The standard resource for measuring job vacancies in the U.S. is the Job Openings and Labor Turnover Survey (JOLTS), conducted by the Bureau of Labor Statistics of the U.S. Department of Labor. The dataset consists of monthly job openings at the national level by major industry category.¹⁷ JOLTS is based on a survey of a random subset of establishments covered by state or federal unemployment insurance laws.¹⁸

Figure A.2 plots the distribution of job ads by sector for JOLTS and EMSI. Certain industries, such as Manufacturing, Finance and Insurance, and Education, have higher representation in EMSI compared with JOLTS, while others, such as Health and Social Assistance, Government, and Accommodation and Food, have higher representation in JOLTS. Overall, however, there is a high correspondence in industries' vacancy shares in the two datasets.

¹⁷The JOLTS dataset also has vacancies at the census region level, but not at the region-by-industry level. JOLTS has no finer geographic unit than census region.

¹⁸JOLTS defines job openings as "positions that are open (not filled) on the last business day of the month. A job is 'open' only if it meets all three of the following conditions: (1) A specific position exists and there is work available for that position. The position can be full-time or part-time, and it can be permanent, short-term, or seasonal; (2) The job could start within 30 days, whether or not the establishment finds a suitable candidate during that time; (3) There is active recruiting for workers from outside the establishment location that has the opening." See https://www.bls.gov/help/def/jl.htm. Accessed February 23, 2021.

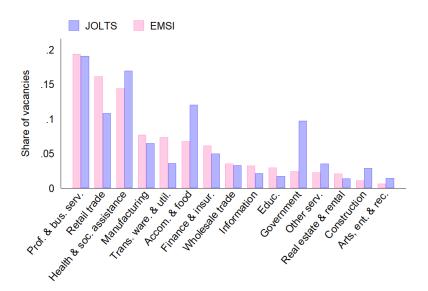

Figure A.2: Distribution of EMSI Job Ads v. JOLTS

This figure plots the distribution of EMSI job ads and JOLTS job openings across major industries, from 2012-2017. The industries are sorted on the x-axis by their share of job ads in EMSI.

A.4 Measuring Occupational Tasks

This section provides additional details on how we measure jobs' task content. These measures correspond to those used in past research: Spitz-Oener (2006) and the O*NET database. We then compare occupations' task content—according to these measures—using the EMSI dataset with measures directly observed in the O*NET database. These two sets of measures align, validating our use of the EMSI dataset.

Mapping Words to Tasks

We map job description words to the five Spitz-Oener (2006) task categories: non-routine analytic, non-routine interactive, non-routine manual, routine cognitive, and routine manual. We use the word-to-task mappings we develop in Atalay et al. (2020). These mappings are available on our project website: https://occupationdata.github.io/. We use the continuous bag of words model list of word mappings, which is described in detail in the data documentation on the website.

Comparing Tasks from Job Ads to O*NET

A key limitation of O*NET is that it only measures tasks at the occupation level. Hence, O*NET is unable to speak to geographic variation in tasks aside from those arising from different employment shares across regions. Nevertheless, O*NET is valuable for testing the validity of our job ads for extracting occupation-level tasks. We construct occupation-level task content using the EMSI ads data and plot the correlation with O*NET's Work Activities.

The specific tasks we compare are O*NET's "Selling or Influencing Others," "Communicating with Persons Outside Organization," "Guiding, Directing, and Motivating Subordinates," "Developing and Building Teams," "Coaching and Developing Others," "Coordinating the Work and Activities of Others," and "Communicating with Supervisors, Peers, or Subordinates." We adopt the mapping of words to O*NET Work Activities listed below.¹⁹ Note that this mapping is necessarily somewhat ad hoc. We count, for each ad, the total number of occurrences of any of the corresponding words. We then normalize the count so that it is expressed per 1,000 job ad words. The first two bullet points refer to interactive tasks that are external to the firm; the remaining five refer to internal interactive tasks.

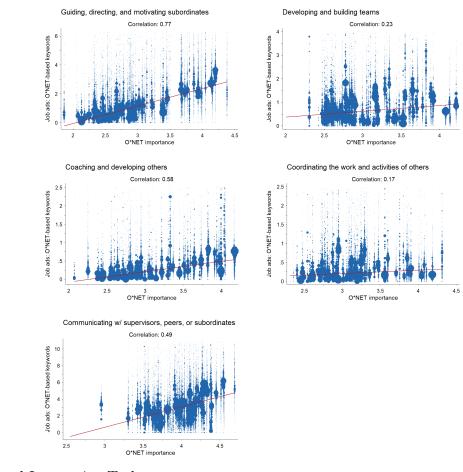

- Selling or Influencing Others: sales marketing advertising advertise merchandising promoting telemarketing market plan
- Communicating with Persons Outside Organization: clients client vendor vendors public interface communicate communication communicating coordinating conferring public relation
- Guiding, Directing, and Motivating Subordinates: directing direction guidance leadership motivate motivating motivational subordinate supervise supervising
- Developing and Building Teams: team-building "team build" project leader
- Coaching and Developing Others: mentor mentoring coaching
- Coordinating the Work and Activities of Others: coordinate coordination coordinator
- Communicating with Supervisors, Peers, or Subordinates: peer subordinate subordinates supervisor supervisors manager managers interface communicate communication communicating coordinating conferring

¹⁹We count instances of each word separately; for example, "public" and "relations" are searched for separately rather than as the bigram "public relations." We make one exception for "team build" because in our judgment "build" on its own is likely to return false positives. In Atalay et al. (2020) and in the word mappings on our project website, some task-related words are bigrams.

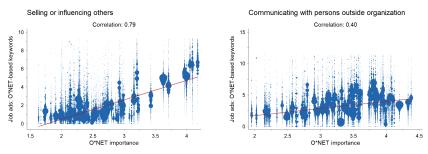

Figure A.3 demonstrates that our job ad-based task data have, for the most part, a high degree of correlation with O*NET tasks. We should not expect a perfect correlation, as O*NET itself has well-known limitations of small sample sizes, status quo bias, and subjective scales (Autor, 2013). But these correlations indicate that the job description text provides meaningful information about the task content of occupations.

Figure A.3: Comparing Tasks from Job Ads with O*NET

I. Internal Interactive Tasks

II. External Interactive Tasks

The figures above plot the correlations between occupation-level tasks extracted from the job ads to those based on O*NET. Each dot represents a four-digit SOC \times CZ. The correlations are weighted by ACS employment. (The figures exclude task intensities over the 99th percentile in both the reported correlations and the scatterplots.)

A.5 Education Requirements: Job Ads v. ACS Employment

In this section, again with the aim of validating the EMSI dataset, we compare education levels across occupations and commuting zones. For each six-digit SOC × CZ, we compute the fraction of job ads requiring a BA degree or above (in ads mentioning an educational requirement) and the fraction of employed workers, measured in the ACS, with a BA degree or higher. Figure A.4 correlates these two measures, with weights for employment in the cell. There is a strong correlation, suggesting that job ads contain valuable information about the educational requirements of the occupation. The share of ads with a given educational requirement is somewhat greater than the corresponding share of workers with that level of educational attainment. This result is perhaps unsurprising, given that job vacancies represent the frontier of occupational change, and the supply of educated workers has increased over time. Figure A.5 plots the same regression by CZ population quartile, showing a strong correlation for both large and small labor markets.

Using the same data, Figure A.6 depicts the gradient of educational requirements across CZ population deciles for the job vacancy data, and, next to it, the gradient of educational attainment of employed workers in the ACS. The gradient looks remarkably similar, both within and across occupations, suggesting again that the job vacancy data are picking up meaningful variation in the educational requirements of jobs across geography.

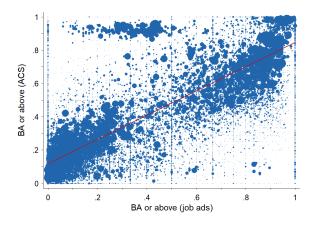

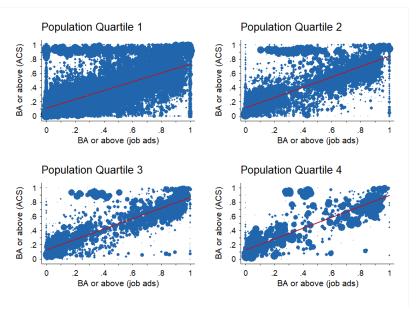

Figure A.4: Education Requirements in ACS v. Job Ads

Each dot in the figure above corresponds to a four-digit SOC \times market. The cells are weighted by employment. The y-axis corresponds to the fraction of workers in the ACS with at least a college degree. The x-axis corresponds to the fraction of job ads that require a BA degree or higher (among ads that mention any education requirement).

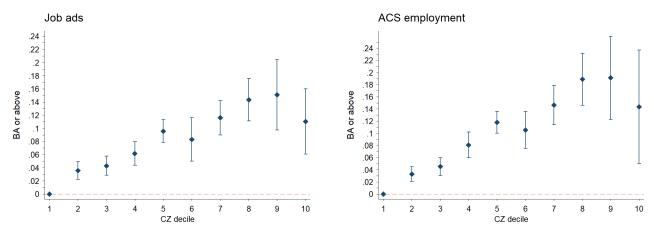

Figure A.5: Education Requirements in ACS v. Job Ads

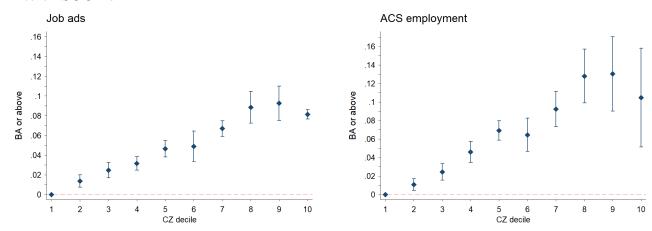

The figure above replicates Figure A.4 separately by CZ population quartile.

Figure A.6: Education Gradient with Market Size: ACS v. Job Ads

I. Without SOC f.e.

II. With SOC f.e.

The top left panel plots the coefficients in a regression of the fraction of job ads having an education requirement of a BA or above (conditional on having an educational requirement) on dummies for CZ decile, in an occupation-market cell. The cells are weighted by employment, and standard errors are clustered at the CZ level. The top right panel plots the same regression except where the dependent variable is the fraction of employed workers with a BA or above. The bottom two panels reproduce the top two panels with four-digit fixed effects.

A.6 Job Ad Length and Description Keywords Across Space

We next consider the content of the job ads and how it differs across geography. First, we plot a binned scatterplot of job ad length (i.e., the number of words) against the log CZ population (Figure A.7). This exercise shows that larger markets have longer job ads on

average. Motivated by this pattern, we control for job ad length throughout our analysis and standardize our task measures to be per 1,000 ad words, and normalize our granular task measures so that each task vector has unit length.

In Appendix B.1, we describe the approach to extracting job tasks from the text. The first step is to first identify the part of the text corresponding to the job description. We use a set of keywords to identify this portion of the ad. Figure A.8 examines the gradient of the job ad containing one of these keywords with market size, after controlling for ad length. The left panel shows a negligible relationship between market size and the presence of a keyword.

Lastly, we show that our novel task-extraction methodology—using job descriptions and parts of speech to let the text define the job tasks—passes a simple validation check. We calculate the cosine similarity between each job and the occupation-market average, and take the average. This exercise reveals that similarity is higher for more narrowly defined occupational categories. Specifically, the cosine similarity is 0.052 for two-digit SOCs, 0.072 for four-digit SOCs, 0.104 for six-digit SOCs, and 0.166 for job titles. Thus, the text-based tasks of occupations are more similar within more narrowly defined occupational categories. It is perhaps unsurprising that narrower occupational categories share more job ad words, but this finding is reassuring and suggests that the text contains valuable information about occupational characteristics that is reflected in standard occupational classifications.

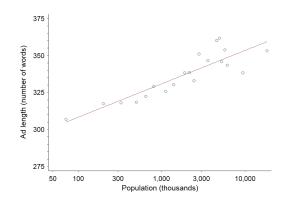

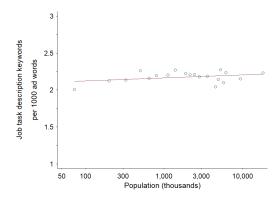

Figure A.7: Job Ad Text Across Geography

The figure above presents a binned scatterplot of job ad length (number of words) on log population at the CZ-level. Cells are weighted by the number of job ads in the cell.

Figure A.8: Job Description Keywords Across Geography

The figure above presents a binned scatterplot of an indicator of the job ad's having a keyword in our task-extraction algorithm—"responsibilities," "duties," "summary," "tasks"—normalized per 1,000 ad words, against log CZ population.

B Task Extraction and Validation

This section outlines our approach to measuring job tasks. We first describe and illustrate the procedure for extracting job tasks from the text (Appendix B.1); present the most common tasks and technologies (Appendices B.2 and B.3); evaluate the relationships among tasks, technologies, and market size (Appendices B.4 and B.5); and show that these tasks account for variation in wages across geography, above and beyond what is captured by occupational codes (Appendix B.6).

B.1 Extracting Job Tasks from the Raw Text

We first use the job ad text to generate a list of job tasks, which we call the *vocabulary of tasks*. Once we have the task vocabulary, we represent each job ad as a vector, of which each element corresponds to a distinct task.

We define a task as a verb-noun pair. There are two main steps in extracting verb-noun pairs from the text:

1. We first isolate the section of the text that pertains to job tasks. To do this we search for keywords in the text that suggest a list of tasks will follow. The keywords we use are "duties," "summary," "description," "tasks." We isolate the section of text that begins

at one of these keywords and ends at the next period.²⁰

2. Using the section of text extracted from step 1, we find all (verb stem, noun stem) pairs, which will make up our task vocabulary. Examples of pairs include "assist customers" and "provide advice." Since verbs and nouns are stemmed, "writing memo" and "writes memos" are recorded as the same task. This step works as follows: We extract each verb and the noun that appears next in the sentence. Hence, if the job ad says "writing lucid memos to prepare for depositions" or "writes legal memos for court hearings," these will both be recorded by our algorithm as "writes memos." If multiple verbs correspond to the same noun (for instance, "prepares and revises memos"), our algorithm extracts two tasks: "prepares memos" and "revises memos." Since many tasks appear only once in the data, we require that the task appear in at least 10 ads to limit the set of tasks in the vocabulary.

Once we have the vocabulary of tasks, according to steps 1 and 2 above, we vectorize all job ads according to the task vocabulary created in step 2. Hence, we are not limiting our analysis to ads with the keywords described in step 1. We represent each ad as a vector, in which each element of the vector corresponds to a particular task in the vocabulary and takes a value of one if the job ad has that particular task and zero otherwise.

B.2 Task List

Below we list the 430 tasks we extract from the job ad text as verb-noun pairs along with the fraction of ads with each task (\times 100).

Tasks Extracted from Verb-Noun Pairs

| written communication | 13.0257 | working store | 0.9374 | bagging merchandise | 0.3460 |
|--------------------------|---------|-------------------|--------|---------------------|--------|
| perform duties | 9.4926 | meet business | 0.9364 | handling cash | 0.3437 |
| working team | 7.4251 | providing product | 0.9180 | procedures cash | 0.3257 |
| provide customer_service | 6.6934 | using equipment | 0.9115 | using eye | 0.3249 |

²⁰The purpose of this step is to eliminate portions of the job ad that refer to worker skills or firm characteristics. This step significantly improves the precision of the task extraction. Note that not all ads will have these keywords, and hence an important check is whether the presence of these words varies systematically from rural to urban labor markets. Figure A.8 investigates this relationship and finds little evidence for a systematic pattern. In step 2, when we vectorize all job ads based on the task vocabulary created in this step, we do not restrict the data to jobs that include these keywords. Also, in step 2, we perform the vectorization on all ad text, not just the portion of text that follows a keyword.

²¹We do not group synonyms, so "write memo" and "draft memo" are recorded as distinct tasks.

²²We do not perform the analogous procedure when a verb is followed by a list of nouns (for instance, "writes memos, opinions, and letters"); in this situation, our algorithm extracts one task—the verb and the first noun ("writes memos").

| be part | 5.6583 | protect company | 0.8972 | taking vehicle | 0.3210 |

As described in the text, we exclude 70 tasks from the original list of 500 most common verb-noun pairs, using our judgment to select pairs that do not correspond to tasks. These excluded verb-noun pairs describe worker skills (e.g., "high school diploma," "ged years,"

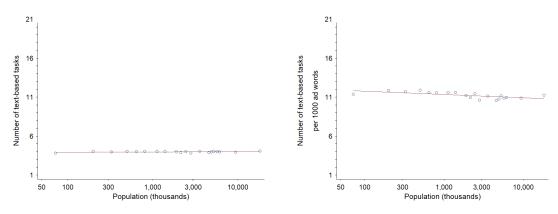

"required bachelor"); firm attributes (e.g., "is company," "is equal_opportunity"); aspects of the job search process ("pass drug"); or are simply uninformative ("meet needs," "be duties"). The excluded verb-noun pairs are:

Verb-Noun Pair Drop List

| | - | |
|----------------------|--------------------|-------------------|
| be years | is position | is delivery |
| is equal_opportunity | work part | are company |
| arc bach | are time | ged years |
| must years | ensure execution | include duties |
| high_school diploma | bach bets | required position |
| demonstrated ability | be team | be duties |
| required employee | travel travel | pass drug |
| bachelor degree | is experience | required bachelor |
| meet needs | may materials | are accordance |
| required ability | are drafts | sporting goods |
| required years | be doors | have ability |
| required skills | can doors | based business |
| according state | are business | ensuring aspects |
| include customers | requested react | assigned job |
| work hours | are store | be ability |
| are customers | including evenings | may duties |
| be customer | is law | are fast_growing |
| preferred years | is customer | requires state |

| s degree | is ability | will business |
| arc setter | send resume | s level |
| end caps | s journal | is job |
| preferred experience | eas program | be company |
| including products | | |
| | | |

Figure B.1 presents the frequency of text-extracted job tasks per ad. The left panel is a binscatter of number of tasks at the ad level on CZ size, while the right panel presents the same figure but first normalizes the number of tasks per 1,000 ad words. There are about four tasks per ad on average (out of 430 total tasks), and when we normalize by ad length, as in the right panel, the number of tasks decreases with market size.

Figure B.1: Number of Tasks and Market Size

The left panel above presents a binned scatterplot of number of tasks against log CZ population. The right panel presents the same figure, except the dependent variable is normalized per 1,000 ad words.

B.3 Technology List

The table below lists the O*NET Hot Technologies that we identify in the job ads text along with the fraction of ads with each technology (\times 100). To be counted as a technology appearance, all words in the technology name must appear in the vacancy text, although we do not require that the words appear in order.

B.4 Tasks and Market Size

Table B.4 presents the tasks with the steepest positive and negative gradients with market size, estimating equation (1). The results broadly support the finding that more interactive tasks and tasks that emphasize teamwork are more common in urban areas. Table B.5 presents the same results, except we include six-digit SOC fixed effects as controls. Table B.6 reruns equation (1) and instead of using our task list extracted from the text itself, we use a predetermined list of verbs from Michaels et al. (2018). The takeaway is quite similar. Using only the verb list, more abstract or non-routine verbs, such as "design," "project," "research," and "manage", have the steepest positive gradient, while more routine verbs, such as "store," "clean," and "count," and manual verbs, such as "fuel" and "rotate," have the steepest negative gradient.

Table B.4: Tasks with the Steepest Gradient: Extracting Tasks Directly from Ads

| Positive gradient | | Negative gradient | | |
|---------------------------|------------------|--------------------------|------------------|--|
| Task | \hat{eta}_{10} | Task | \hat{eta}_{10} | |
| written communication | 0.1596 | maintain store | -0.1763 | |
| managing projects | 0.1157 | maximizes profitability | -0.1692 | |
| committed diverse | 0.1100 | operating cash_register | -0.1653 | |
| meet deadlines | 0.1075 | protect company | -0.1641 | |
| providing support | 0.0956 | make changes | -0.1431 | |
| maintaining relationships | 0.0943 | provide customer_service | -0.1394 | |
| written skills | 0.0922 | preventing trafficking | -0.1373 | |
| work environment | 0.0910 | greeting customers | -0.1343 | |
| problem_solving skills | 0.0881 | skating carhop | -0.1334 | |
| required knowledge | 0.0844 | procedures cash | -0.1264 | |
| working relationships | 0.0844 | maintaining inventory | -0.1234 | |
| develop business | 0.0833 | assist store | -0.1221 | |
| developing strategies | 0.0754 | unloading trucks | -0.1191 | |
| identify opportunities | 0.0751 | ensure employees | -0.1143 | |
| prioritize tasks | 0.0739 | drive_in employees | -0.1104 | |

We estimate equation (1) separately for each task, excluding controls. We normalize the estimates by dividing by the standard deviation of the task. The table above presents the tasks with the steepest positive and negative gradients with respect to market size, as captured by $\hat{\beta}_{10}$, which reflects the difference between 10th and 1st decile market size. All coefficients are statistically significant at the 1 percent level.

Table B.5: Tasks with the Steepest Gradient: Extracting Tasks Directly from Ads (with SOC f.e.)

| Positive gradient | | Negative gradient | | |
|-----------------------|------------------|--------------------------|------------------|--|
| Task | \hat{eta}_{10} | Task | \hat{eta}_{10} | |
| committed diverse | 0.0915 | maximizes profitability | -0.1597 | |
| achieving sales | 0.0701 | protect company | -0.1501 | |
| ensure safety | 0.0686 | maintain store | -0.1339 | |
| written skills | 0.0580 | operating cash_register | -0.1256 | |
| stand walk | 0.0573 | make changes | -0.1249 | |
| driving sales | 0.0572 | greeting customers | -0.1094 | |
| exceed sales | 0.0556 | procedures cash | -0.1080 | |
| work environment | 0.0541 | skating carhop | -0.1064 | |
| providing environment | 0.0523 | ensure employees | -0.1041 | |
| providing coaching | 0.0510 | unloading trucks | -0.1005 | |
| according company | 0.0500 | drive_in employees | -0.0981 | |
| prioritize tasks | 0.0500 | maintaining inventory | -0.0948 | |
| working relationships | 0.0488 | assigned store | -0.0873 | |
| handle tasks | 0.0487 | working store | -0.0852 | |
| using eye | 0.0461 | provide customer_service | -0.0848 | |

The table above reproduces Table B.4 with six-digit SOC f.e. as controls. All estimates are statistically significant at the 1 percent level.

Table B.6: Verbs with the Steepest Gradient

| Positive gradient | | Negative gradient | | |
|-------------------|------------------|-------------------|------------------|--|
| Task | \hat{eta}_{10} | Task | \hat{eta}_{10} | |
| design | 0.0812 | pay | -0.0625 | |
| project | 0.0797 | truck | -0.0623 | |
| experience | 0.0660 | store | -0.0559 | |
| research | 0.0632 | earn | -0.0513 | |
| develop | 0.0616 | clean | -0.0506 | |
| manage | 0.0581 | license | -0.0452 | |
| web | 0.0560 | fuel | -0.0448 | |
| finance | 0.0499 | get | -0.0421 | |
| analyze | 0.0492 | rotate | -0.0396 | |
| process | 0.0483 | authorize | -0.0392 | |
| create | 0.0461 | count | -0.0362 | |
| content | 0.0437 | trash | -0.0321 | |
| lead | 0.0432 | average | -0.0320 | |
| market | 0.0431 | retail | -0.0307 | |
| track | 0.0426 | sign | -0.0301 | |

The table above reproduces Table B.4, except it uses the list of verbs from Michaels et al. (2018) as tasks instead of the verb-noun pairs extracted from job descriptions. This exercise is conducted on a 1 percent sample of all job ads, rather than 5 percent, for computational speed, since the verb list includes 1,665 verbs. All estimates are statistically significant at the 1 percent level.

B.5 Technology Requirements and Market Size

Table B.7 re-estimates equation (1) where the dependent variable is a specific technology requirement. We estimate this regression separately for each O*NET technology and report the technologies with the steepest positive gradient with respect to market size. We estimate equation (1) using the entire sample of job ads, using the subsample of those requiring a high school degree only, and using the subsample requiring a college degree or above.

Table B.7 has several implications. First, the magnitude of the technology gradient is stronger for technologies requiring a college degree than a high school degree. Second, the technologies required of higher-skilled workers are more advanced and include computer programming (e.g., Python, Linux, Javascript, Unix) and not simply word processing (e.g., the Microsoft Office suite) or social media (e.g., Facebook, LinkedIn).²³

²³Table B.7 omits technologies with the steepest negative gradient because the estimates are small in magnitude and only two are statistically significant at the 5 percent level. First, pooling all ads, the coefficient estimate for Swift is -0.0593 and is significantly different from 0. It is likely that for many job ads, "swift" is simply an adverb and not a reference to a technological requirement. For jobs requiring a high school degree, no technologies have a negative gradient that are statistically significant. For jobs requiring a college degree

Lastly, we check the sensitivity of our result on the market size gradient of technologies with respect to our decision to exclude R and C from the technology list. Figure B.2 reproduces Figure 3 but includes the technologies R and C, which are potentially susceptible to false positives in processing the job vacancy text. Our main result is largely unaffected.

Table B.7: Technologies with the Steepest Gradient

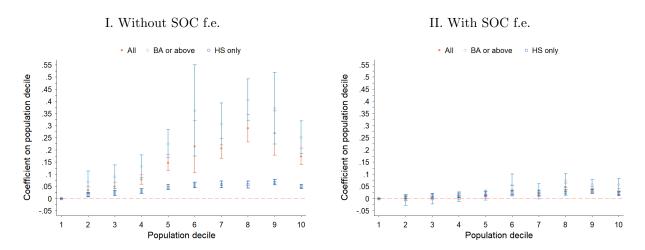

| All | | College | | High School | |
|-------------------------------------|------------------|----------------------|------------------|----------------------|------------------|
| Technology | \hat{eta}_{10} | Technology | \hat{eta}_{10} | Technology | \hat{eta}_{10} |
| Microsoft Excel | 0.1131 | Python | 0.0980 | Microsoft Excel | 0.0721 |
| Python | 0.0843 | Microsoft Excel | 0.0889 | LinkedIn | 0.0689 |
| Microsoft Project | 0.0789 | Javascript | 0.0844 | Microsoft Outlook | 0.0527 |
| Linux | 0.0785 | SAS | 0.0710 | Facebook | 0.0469 |
| Microsoft Office | 0.0720 | Linux | 0.0708 | Microsoft Word | 0.0453 |
| SAP | 0.0686 | Microsoft Project | 0.0706 | Microsoft Office | 0.0412 |
| Microsoft Access | 0.0685 | Microsoft Access | 0.0650 | Youtube | 0.0334 |
| Microsoft Powerpoint | 0.0680 | Git | 0.0644 | React | 0.0277 |
| Microsoft Outlook | 0.0630 | MySQL | 0.0591 | Microsoft Access | 0.0250 |
| LinkedIn | 0.0621 | Facebook | 0.0558 | Microsoft Powerpoint | 0.0239 |
| Unix | 0.0589 | Tax Software | 0.0553 | Objective C | 0.0216 |
| Facebook | 0.0589 | Microsoft Office | 0.0550 | Python | 0.0179 |
| SAS | 0.0584 | Unix | 0.0549 | Ajax | 0.0170 |
| Geographic Information System (GIS) | 0.0579 | Ajax | 0.0542 | Yardi | 0.0167 |
| Git | 0.0563 | Microsoft SQL Server | 0.0531 | Citrix | 0.0164 |

We estimate equation (1) where the dependent variable is a specific technology requirement, excluding controls. We estimate this regression separately for each O*NET technology. All coefficients are normalized by dividing by the standard deviation of the technology. We report the technologies with the steepest positive gradient with respect to market size, $\hat{\beta}_{10}$, which reflects the 10th decile technology intensity relative to the 1st decile. All estimates are statistically significant at the 5 percent level, with the following exceptions in the High School column: React (p = 0.48) and Ajax (p = 0.09).

47

or above, only Apache Pig has a statistically significant negative gradient (-0.0134).

Figure B.2: The Technology Gradient (including R and C)

The figure above reproduces Figure 3 but includes the technologies R and C.

B.6 Wages and Tasks Across Space

This section demonstrates that tasks extracted from job vacancy ads account for variation in wages across geography, above and beyond what is captured by occupational codes.

For this analysis, we construct occupation-education-market average tasks from the job ads data. We then merge mean wages at the occupation-education-market level from the IPUMS-ACS. We then regress log wages on tasks, with different sets of controls. All regressions are weighted by employment in the cell.

Note that these regressions probably understate the explanatory power of job tasks in accounting for wage variation, since we do not observe job-level wages and these are regressions of mean wages on mean tasks, using variation across geography-education cells. While it is tempting to interpret these estimates as hedonic regressions that are delivering "task prices," we should avoid this interpretation because tasks are endogenous to unobserved worker sorting or job characteristics.

Table B.8 first shows that task variation across geography accounts for variation in wages above and beyond what is captured by occupation fixed effects. This result can be seen by the statistically significant coefficients on tasks in columns 3-6. Note that the slight increase in R^2 between columns 2 and 3 indicates that the five task categories only capture 0.1 percent of wage variation beyond occupation categories. But the granular task measures account for an additional 1.9 percent of wage variation, as seen by comparing R^2 between columns 3 and 4. Thus, the granular tasks extracted from job descriptions capture meaningful information about job tasks that are reflected in wages. Note that for jobs requiring a college degree,

non-routine analytic tasks have a stronger relationship with wages than for jobs requiring a high school degree only.

Table B.9 presents regressions of log wages on log population, tasks, and tasks interacted with population. In the coefficient on log-population, we confirm the finding in the literature that the relationship between population and wages is stronger for higher educated workers. We also see that the interaction terms between population and tasks appears important. For example, column 2 shows that an increase in interactive tasks in larger labor markets accounts for higher wages of jobs requiring a college degree, while an increase in interactive tasks for jobs requiring a high school degree has a weaker correlation with wages. Note that this table uses within-occupation variation in tasks across geography in accounting for higher wages. Overall, Tables B.8 and B.9 show that task variation across space accounts for variation in wages above and beyond occupation codes.

Table B.8: Wages and Tasks

| | | Baseline | | | | BA or above | |
|-------------------------------------|--------------------------|-----------------|----------------------|---------------------|----------------------|--------------------------|--|
| | (1) | (2) | (3) | (4) | (5) | (6) | |
| Non-routine analytic | 0.229*** (0.013) | | 0.050*** (0.010) | 0.042*** (0.012) | 0.020** (0.008) | 0.060*** (0.016) | |
| Non-routine interactive | 0.085*** (0.012) | | -0.003 (0.006) | -0.009 (0.006) | 0.013 (0.010) | -0.005 (0.009) | |
| Routine cognitive | -0.008** (0.004) | | -0.021*** (0.004) | -0.002 (0.004) | -0.025*** (0.005) | -0.014 (0.011) | |
| Routine manual | 0.059^{***} (0.005) | | -0.018*** (0.006) | -0.007 (0.005) | -0.020*** (0.006) | -0.056*** (0.011) | |
| Non-routine manual | 0.040*** (0.008) | | 0.010^* (0.005) | 0.002 (0.005) | $0.005 \\ (0.005)$ | -0.057^{***} (0.013) | |
| SOC f.e. Text-based tasks | No No | Yes No | Yes No | Yes Yes | Yes No | Yes No | |
| Number of observations R^2 | 58,494 0.489 | 58,494 0.784 | 58,494 0.785 | 58,494 0.804 | 33,859 0.552 | 24,635 0.694 | |
| Adjusted R^2 Mean of dep. var. | 10.65 | 0.784 10.65 | $0.785 \\ 10.65$ | 0.803 10.65 | $0.551 \\ 10.44$ | 0.693 10.94 | |

The unit of observation is the occupation-education-market. The dependent variable is log wages, regressed on Spitz-Oener (2006) task-related keywords per 1,000 ad words, which are standardized to have mean zero and standard deviation one across ads before averaging to the cell. Column 4 includes the verb-noun tasks averaged to the cell. The only controls are education category dummies and four-digit SOC f.e., which are included in columns 2-5. Regressions are weighted by employment. Standard errors are clustered at the CZ level.

Table B.9: Wages and Task-Population Gradient

| | HS only | BA or above |
|---|---------------------------------|---------------------------------|
| | (1) | (2) |
| Log pop. × non-routine analytic | 0.043*** (0.006) | 0.013*** (0.004) |
| Log pop. × non-routine interactive | 0.015** (0.006) | $0.029^{***} $ (0.006) |
| Log pop. × routine cognitive | 0.002 (0.002) | $0.009 \\ (0.007)$ |
| $\begin{array}{l} \text{Log pop.} \\ \times \text{ routine manual} \end{array}$ | -0.018*** (0.003) | -0.012*** (0.004) |
| $\begin{array}{l} {\rm Log~pop.} \\ {\rm \times~non\text{-}routine~manual} \end{array}$ | 0.002 (0.003) | -0.014 (0.009) |
| Log population | 0.076*** (0.007) | 0.081*** (0.008) |
| SOC f.e. Number of observations \mathbb{R}^2 Mean of dep. var. | Yes 33,859 0.594 10.44 | Yes 24,635 0.766 10.94 |

The unit of observation is the occupation-education-market. The dependent variable is log wages, which is regressed on four-digit SOC f.e., tasks, log population, and log population interacted with tasks. Tasks are standardized to have mean zero and standard deviation one across ads before averaging to the cell. Regressions are weighted by employment. Task coefficients are not reported above. Standard errors are clustered at the market level. Tasks correspond to the classification in Spitz-Oener (2006).

C Analysis Appendix

This section presents tables and figures to supplement the main analysis.

C.1 Task Differences Across Geography: Within and Between Occupations

To evaluate whether the variation in occupational tasks across geography is due to withinversus between-occupation variation in task content, we perform a simple decomposition. Denote the average task k content in market size quartile q as, $t_{kq} = \sum_{o \in \mathcal{O}} t_{koq} s_{oq}$, where the average task content of each occupation o in quartile q, t_{koq} , is multiplied by occupation o's share of quartile q's employment, s_{oq} . We express the difference in task content between

two quartiles, q and \tilde{q} , as

$$t_{kq} - t_{k\tilde{q}} = \sum_{o \in \mathcal{O}} (t_{koq} - t_{ko\tilde{q}}) \bar{s}_{oq\tilde{q}} + \sum_{o \in \mathcal{O}} \bar{t}_{koq\tilde{q}} (s_{oq} - s_{o\tilde{q}}), \tag{4}$$

where $\bar{s}_{oq\tilde{q}} = (s_{oq} + s_{o\tilde{q}})/2$ and $\bar{t}_{koq\tilde{q}} = (t_{koq} + t_{ko\tilde{q}})/2$. The first term on the right-hand side of equation (4) represents the within component, and the second term represents the between component. Dividing both sides by $(t_{kq} - t_{k\tilde{q}})$ yields the within and between shares.

Table C.1 presents the results of this decomposition. For non-routine analytic tasks, 23 percent of the variation between 1st quartile and 4th quartile CZs is within occupation. For non-routine interactive tasks, the corresponding figure is 35 percent. This result implies that standard data sources fail to capture much of the variation in tasks between rural and urban markets.

NR-Analytic NR-Interactive NR-Manual R-Cognitive R-Manual Q1 0.84 0.64 2.98 4.39 4.73 \dot{Q}_2 4.76 5.18 0.77 0.67 2.86 5.13 5.63 0.790.702.70 2.31 7.07 6.41 0.78 0.77Between and Within Occupational Decomposition Between Within Between Within Between Within Between Within Between Within Q2-Q1 0.61 0.390.430.57 0.540.46 0.860.140.64 0.36 Q3-Q2 0.73 0.27 0.650.35 0.39 0.61 1.68 -0.68 0.40 0.60 Q4-Q3 0.81 0.19 0.780.22-0.161.16 1.22 -0.220.57 0.43Q4-Q1 0.23 0.65 0.770.35 0.50 0.501.06 -0.060.56 0.44

Table C.1: Summary Statistics: Task Decomposition Across Markets

The top panel plots the average task content in each of four market size quartiles. Tasks are expressed as number of task-word mentions per 1,000 ad words. The bottom panel presents a decomposition of the within and between shares of the total difference between population quartiles.

C.2 Appendix to Section 3.1

In this appendix, we present additional figures on the relationships among job tasks and population.

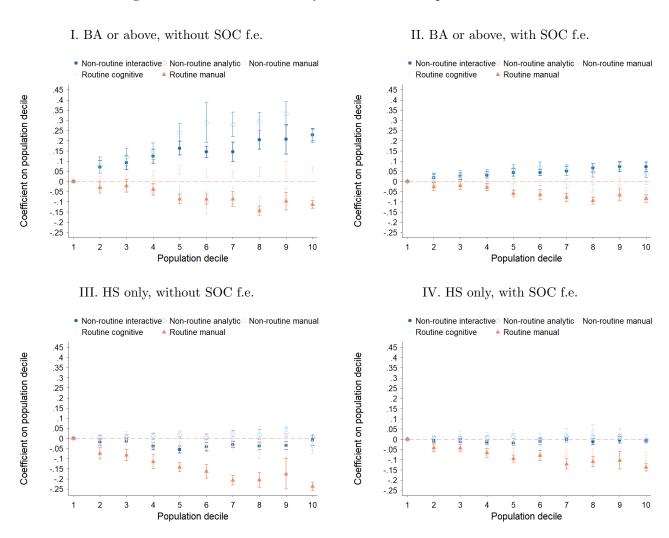

In Figure 1 of the paper, we demonstrate that non-routine interactive and non-routine analytic tasks are mentioned more frequently in larger markets, and routine manual and routine cognitive tasks less frequently. In Figure C.1, we demonstrate that these relationships are primarily due to differences among ads that require a college degree.

Figure C.2 considers whether there is evidence for jobs being jointly intensive in interactive and analytic tasks in large markets, as Deming (2017) finds them to be increasingly

important over time. We place each job into one of four groups, based on whether it is above or below the median non-routine interactive task content, and above or below the median non-routine analytic task content. We then plot, for each decile, the difference between the proportion of jobs in each of the four groups relative to the proportion of jobs in the same group in the first CZ decile. This plot is presented as the left panel of Figure C.2. We find that jobs that are intensive in both analytic and interactive tasks make up 15 percentage points more of jobs in each of the highest three deciles compared with the lowest decile. Jobs that are intensive in only analytic tasks but not interactive tasks make up only about 4 percentage points more of jobs in the highest three deciles, while jobs that are only interactive but not analytical make up a smaller share of total jobs in the highest decile markets, relative to smallest decile markets. This finding holds even after removing the mean task content at the six-digit SOC level before categorizing into the four groups, as seen in the right panel of Figure C.2.

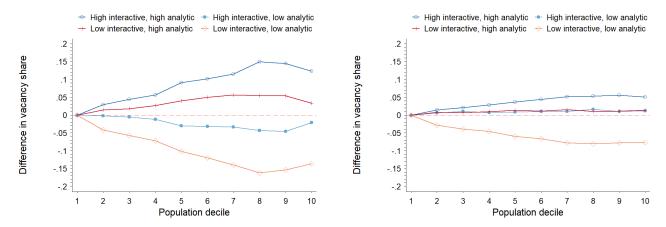

In Figure C.3, we explore whether the gradients presented in Figure 2 differ according to the jobs' educational requirements. For the most part, gradients are steeper for jobs requiring a college degree. However, in specifications with six-digit SOC occupation fixed effects, the difference between these gradients is minor.

Figure C.1: Task Gradient by Educational Requirements

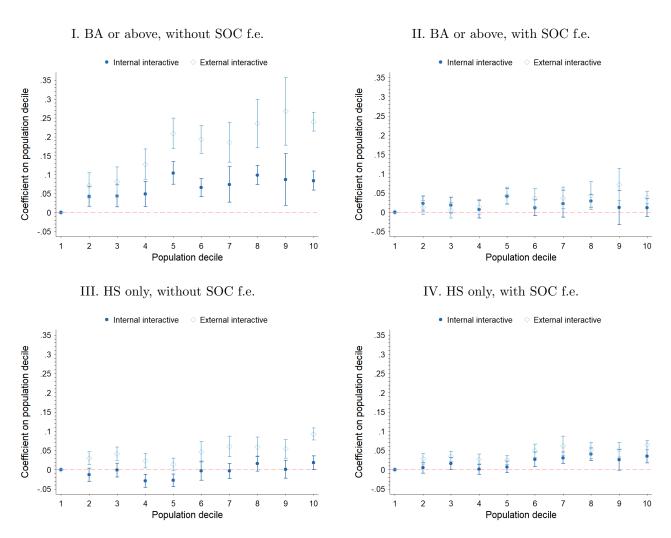

This figure reproduces Figure 1 separately by the educational requirement of the job. Panels I and II restrict the sample to ads requiring a BA or above, while panels III and IV restrict the sample to ads requiring high school only.

Figure C.2: Interactive and Analytic Tasks and Market Size

The panels above depict the distribution of jobs across space. To construct the left panel, we first place job ads into one of four mutually exclusive groups, based on whether they are above or below the median non-routine interactive task content and non-routine analytic task content. We then plot the difference between the proportion of jobs in each of the four categories (high or low, analytic or interactive) relative to the proportion of jobs in the same category in the first CZ decile. The right panel is constructed in the same way, except we first subtract the SOC mean task content from each job before placing jobs into groups, and hence the right panel reflects within-occupation changes in task content across space.

Figure C.3: O*NET Interactive Tasks Gradient

This figure reproduces Figure 2 separately by the educational requirement of the job. Panels I and II restrict the sample to ads requiring a BA or above, while panels III and IV restrict the sample to ads requiring high school only.

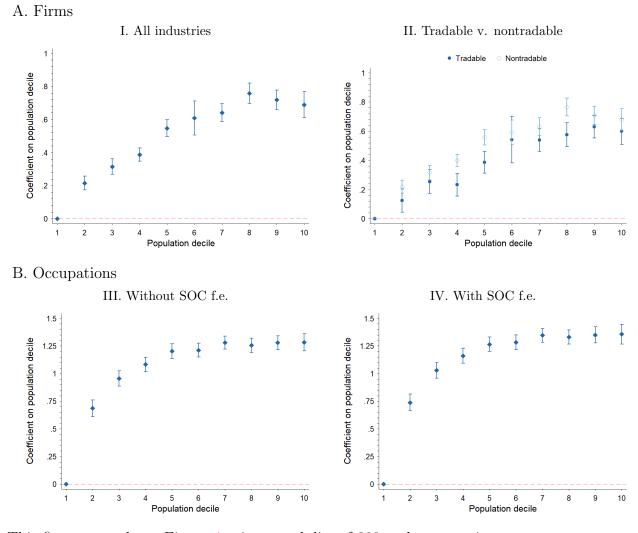

C.3 Specialization and Market Size

This section provides supplemental evidence on the relationship between specialization within and between firms and market size.

Robustness to the Number of Tasks

Our measurement approach requires setting a threshold for the number of tasks (verb-noun pairs) we use to study specialization. In the paper, we use a task list of 500 verb-noun pairs, which we winnow to 430 by excluding those that, according to our judgment, do not reflect job tasks. In this section, we reduce the number of tasks to 300—i.e., keeping the most common 300 of the 430 remaining tasks—and reproduce Figure 4, the main figure that uses these granular task measures. Figure C.4 shows that the results are not sensitive to the choice of number of tasks.

Figure C.4: Specialization Gradient: Task Dissimilarity Within Firms and Occupations (300 Tasks)

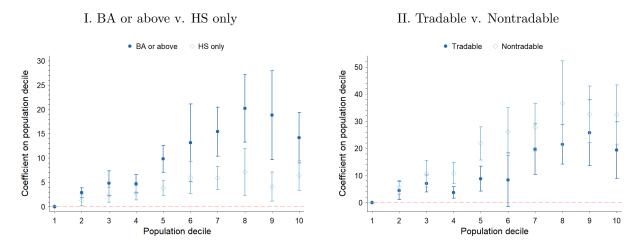

This figure reproduces Figure 4 using a task list of 300 verb-noun pairs.

Number of Job Titles

Prior research—notably, Tian (2019)—examines evidence for specialization by counting the number of distinct occupation codes in a firm-market. The idea behind this exercise is that a greater number of distinct occupations implies greater specialization in production. We examine this relationship in Figure C.5, using our job vacancy data to count distinct job titles within a firm name \times six-digit industry NAICS \times CZ. We produce these market size gradients separately for high- and low-education-level job titles, and for tradable and nontradable sector firms. The key takeaway is that we do see a positive relationship between market size and the degree of worker specialization, and this relationship is stronger for workers with a BA degree or above and for nontradable sector firms.

Figure C.5: Specialization Gradient: Number of Job Titles

The unit of observation is the firm-market (CZ). We regress the number of distinct job titles on market size deciles, controlling for the total number of ads placed by the firm in the CZ, two-digit NAICS code, and the average log ad length. The left panel depicts two regressions. In the first, the dependent variable is the number of job titles requiring a high school degree, and in the second, the dependent variable is the number of distinct job titles requiring a college degree. In the right panel, the dependent variable is the number of distinct job titles, and the regression is estimated separately on tradable and nontradable sector firms. All regressions are weighted by the number of ads in the firm-market. Standard errors are robust and clustered at the CZ level. The figure plots the coefficients on the CZ size deciles. For reference, in the left panel, the 1st decile CZ mean for BA or above is 2.58 and for HS only is 3.11. In the right panel, the 1st decile CZ mean for tradable is 9.96 and for nontradable is 10.68.

The Distribution of Common and Rare Occupations

As another robustness exercise, we measure the degree of specialization by examining the distribution of common and rare occupations across space.

We rank six-digit SOCs based on their share of all ads in the full sample. The x-axis presents SOCs in descending order based on their overall rank in the sample. We then compute the share of each SOC in each market size decile and plot the difference relative to the share in the 1st decile CZ. The left panel of Figure C.6 shows that the most common occupations are overrepresented in small markets, while more rare occupations are overrepresented in large markets. For example, of the 10 most common occupations economy-wide, the 10th decile market has 11-13 percentage points lower share of these occupations compared with the 1st CZ decile. For the 300-400 most common occupations, the 10th decile market has about a 0.3 percentage point greater share relative to the 1st decile.

This finding—that rare jobs represent a larger share of total jobs in larger markets—is even more pronounced when we perform the analysis at the job title level. Note that the job title is not observed in standard datasets such as the ACS or the Current Population Survey (CPS), and hence represents an additional virtue of the job ads data used here. The right panel presents the analysis at the job title level, showing even more dramatically that common jobs are overrepresented in smaller markets (as a share of total jobs).

1st decile 2th decile 5th decile 1st decile 2th decile 5th decile 8th decile - 10th decile 8th decile 10th decile .01 .01 -.01 -.01 -.03 -.03 Difference in CDF relative to 1st decile Difference in CDF relative to 1st decile -.05 -.05 -.07 -.07 -.09 -.09 -.11 0 300 1500 2000 2500 3000 3500 4000 100 200 400 500 600 700 800 0 500 1000 SOC rank (across job ads) Job title rank (across job ads)

Figure C.6: Common and Rare Occupations and Job Titles

The left panel is constructed as follows. We first generate the empirical cdf of occupational shares for each CZ decile. On the x-axis, the six-digit SOCs are ranked in order of their shares of all job ads in the sample, from highest to lowest. The left panel presents the difference between each CZ decile cdf and the 1st decile CZ's cdf. The right panel is constructed analogously, except the unit of analysis is the job title rather than the six-digit SOC. A local polynomial smoother is applied to both panels.

Specialization Across Firms

In Section 3.3, we considered the relationship between market size and within-firm specialization. In this appendix, we consider specialization across firms. The unit of analysis in this section is the industry-market, and the degree of specialization is computed across firms in the industry-market.

Define the dissimilarity between firm f in industry i and market m and other firms in the industry-market as $d_{fim} = 1 - \overline{V}_{fim} \cdot \overline{V}_{(-f)im}$. In this equation, \overline{V}_{fim} is the vector of average tasks for the firm-industry-market, and $\overline{V}_{(-f)im}$ is the vector of average tasks for all firms other than f in the industry-market. The dependent variable in this analysis of across-firm specialization is $d_{im} = \frac{1}{n_{im}} \sum_{f,m} d_{fim}$, where n_{im} is the number of firms in the industry-market cell.

Table C.2 presents regressions at the industry-market level. There are three takeaways: In larger markets, (1) there are more firms, (2) firms have more workers, and (3) firms are further apart in task space. These effects are larger for the nontradable sector.

Taking these results together with those of Section 3.3, both within- and between-firm specialization increase with market size.

Table C.2: Specialization Across Firms

| | Mean | OLS | | | |
|---|--------------------|---------------------------------------|---------------------------------------|--------------------------------------|--------------------------------------|
| Firm size | 3.544 (4.409) | (1) 0.892*** (0.047) 103,501 | (2) 1.093*** (0.057) 103,501 | (3) 0.693*** (0.053) 20,560 | (4) 1.158*** (0.061) 82,273 |
| Number of firms | 18.237 (32.266) | 8.968*** (0.728) 103,501 | 9.374*** (0.675) 103,501 | 1.500*** (0.131) 20,560 | 8.090*** (0.591) 82,273 |
| Task dissimilarity between firms | 0.895 (0.158) | 0.023*** (0.001) 46,331 | 0.027*** (0.002) 46,331 | 0.018^{***} (0.002) 5,528 | 0.029*** (0.002) 40,144 |
| NAICS f.e. Tradable sector only Nontradable sector only | | | Yes | Yes Yes | Yes Yes |

The unit of analysis is the industry-market. Each cell in columns 1-4 is a separate regression of the dependent variable indicated in the row on log CZ population. The estimate for log CZ population is presented along with the standard error (in parentheses) and the number of observations. Task dissimilarity between firms is the dissimilarity between the firm-level average and the leave-out firm average in the industry-market. Firm size is measured as the total number of job ads in the market, and the number of firms is measured as the number of firms with a posting in the industry-market cell. The only controls included are average log total ad words in the cell and, where indicated, the six-digit NAICS code. Regressions are weighted by the number of firms. Standard errors are clustered at the CZ level.

C.4 Robustness to Data Source

In this appendix, we reproduce some of our main empirical exercises using a sample of ads from Burning Glass. Our EMSI dataset has its own advantages. In particular, it contains the ads' raw text, allowing us to isolate the tasks that employers list. In contrast, Burning Glass commingles jobs' skills, technologies, and tasks. Nevertheless, since Burning Glass has been so commonly used in recent analyses of the labor market, we check the robustness of our results to this alternate data source.

We draw a random sample of 1.2 million ads from January 2012 to December 2017. For this sample, so that we can replicate Figure 2, we compute measures of internal-to-thefirm interactive tasks²⁴ and external-to-the-firm interactive tasks.²⁵ As in Section 3.1, we compute the number of task mentions per 1000 ad words. Second, as in Section 3.2, for each ad we compute whether the ad mentions individual O*NET Hot Technologies. So that we can compute specialization, as in Section 3.3, for each job ad j we define a 400-dimensional vector, T_j , with each element characterizing whether ad j mentions the individual Burning Glass element. As in Section 3.3, we define the normalized task vectors $V_j = \frac{T_j}{\sqrt{T_j \cdot T_j}}$, and the distance between job j and other jobs in the occupation- (or firm-) and market as $d_{jcm} = 1 - V_{jcm} \cdot \overline{V}_{(-j)cm}$.

First, Figure C.7 replicates Figure 2. As in Section 3.1, external tasks increase in city size, both within and between six-digit SOC occupations. However, potentially due to the smaller sample size, the relationship between city size and internal tasks is no longer statistically significant.

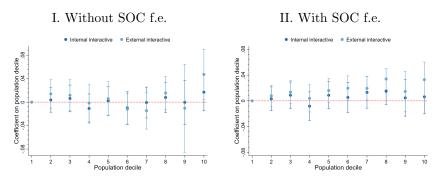

Second, we reproduce Figure 4. As in Figure 4, Figure C.8 indicates that within-occupation and within-firm specialization is greater in more populous commuting zones, with a steeper gradient for firms in nontradable industries than for firms in tradable industries (panel II).

Finally, we reproduce Table 1. As in Table 1, Table C.3 indicates that wages are higher in markets with greater specialization, with greater technology usage, and with a greater share of workers with a college degree. The relationships between wages and within-occupation × market specialization is stronger in white-collar than in blue-collar occupations. In contrast to Table 1, however, the association between wages and technology mentions is stronger in blue-collar occupations.

²⁴We map the following Burning Glass elements to internal interactive tasks: "Agile coaching," "Communication Skills," "Employee Coaching," "Executive Coaching," "Leadership," "Leadership Development," "Leadership Training," "Mentoring," "Oral Communication," "Peer Review," "Personal Coaching," "Supervisory Skills," "Team Building," "Verbal / Oral Communication," and "Written Communication."

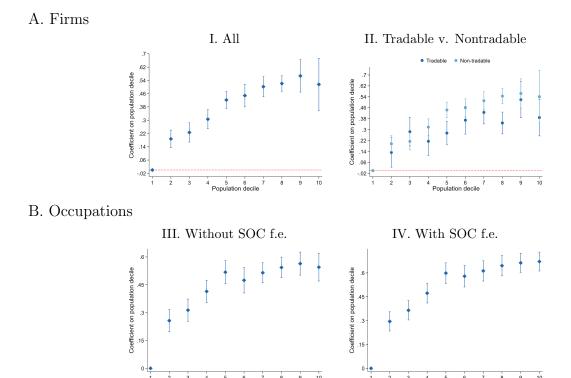

²⁵We map the following Burning Glass elements to external interactive tasks: "Advertising," "Client Base Retention," "Client Care," "Client Needs Assessment," "Client Relationship Building and Management," "Communication Skills," "Digital Marketing," "Market Planning," "Marketing," "Marketing Communications," "Marketing Programs," "Marketing Sales," "Marketing Strategy Development," "Merchandising," "Oral Communication," "Print Advertising," "Product Marketing," "Professional Services Marketing," "Prospective Clients," "Public Relations," "Public Relations Campaigns," "Public Relations Industry Knowledge," "Public Relations Strategy," "Sales," "Telemarketing," "Vendor Interaction," "Vendor Performance Monitoring," "Vendor Relations," "Verbal / Oral Communication," and "Written Communication."
